### AI PHASE 2:

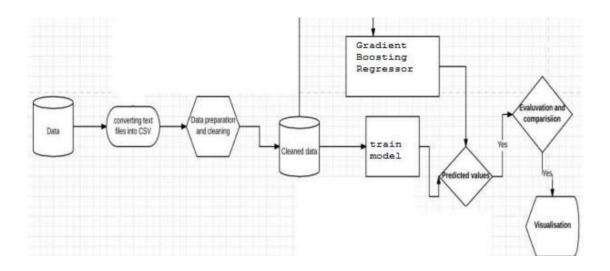

Consider exploring advanced regression techniques like XG Boost for Improved prediction accuracy.

#### PROPOSED SYSTEM:

In this proposed system, we focus on predicting the house price values using machine learning

algorithms like XG Boost regression model. We proposed the system "House price prediction using Machine Learning" we have predicted the House price using XG boost regression model. In this proposed system, we were able to train the machine from the various attributes of data points from the past to make a future prediction. We took data from the previous year stocks to train the model .The data set we used was from the official organization. Some of data was used to train the machine and the rest some data is used to test the data. The basic approach of the supervised learning model is to learn the patterns and relationships in the data from the training set and then reproduce them for the test data. We used the python pandas library for data processing which combined different datasets into a data frame. The raw data makes us to prepare the data for feature identification. The attributes were stories, no. of bed rooms, bath rooms, Availability of garage, swimming pool, fire place, year built, area in soft, sale price for a particular house. We used all these features to train the machine on XG boost regression and predicted the house price, which is the price for a given day. We also quantified the accuracy by using the predictions for the test set and the actual values. The proposed system gives the Predicted price.

#### ARCHITECTURE:

#### ALOGORITHM:

We used the python pandas library for data processing which combined different datasets into a data frame. The raw data makes us to prepare the data for feature identification. XG for regression builds an additive model in a forward stage wise fashion. It allows for the optimization of arbitrary differentiable loss functions. In each stage, a regression tree is fit on the negative XG of the given loss function. The idea of boosting came out of the idea of whether a weak learner can be modified to become better. A weak hypothesis is defined as one whose performance is at least slightly better than random chance. The Objective is to minimize the loss of the model by adding weak hypothesis using a XG descent like procedure. This class of algorithms was described as a stage-wise additive model. This is because one new weak learner is added at a time and existing weak learners in the model are frozen and left unchanged.

```
Step 1: Load the data set df = pd.read csv("ml_house_data_set.csv")
```

- Step 2: Replace categorical data with one-hot encoded data
- Step 3: Remove the sale price from the feature data
- Step 4: Create the features and labels X and Y arrays.
- Step 5: Split the data set in a training set (70%) and a test set (30%). Step 6: Fit regression model.
- Step 7: Save the trained model to a file trained house classifier model.pkl
- Step 8: Predict house worth using predict function

#### MODEL XG BOOST REGRESSOR:

**INPUT:** 

```
model_xg = xg.XGBRegressor()
```

```
model_xg.fit(X_train_scal, Y_train)
OUTPUT:
```

#### XGB Regressor

```
XGB Regressor (base_score=None, booster=None, callbacks=None, colsample_bylevel=None, colsample_bynode=None, colsample_bytree=None, early_stopping_rounds=None, enable_categorical=False, eval_metric=None, feature_types=None, gamma=None, gpu_id=None, grow_policy=None, importance_type=None, interaction constraints=None, learning rate=None, max bin=None,
```

```
max_cat_threshold=None, max_cat_to_onehot=None, max_delta_step=None, max_depth=None, max_leaves=None, min_child_weight=None, missing=nan, monotone_constraints=None, n_estimators=100, n_jobs=None, num_parallel_tree=None, predictor=None, random_state=None, ...)
```

#### PREDICTING PRICES:

```
Prediction5 = model_xg.predict(X_test_scal)

EVALUATION OF PREDICTING DATA:

INPUT:

plt.figure(figsize=(12,6)) plt.plot(np.arange(len(Y_test)), Y_test, label='Actual Trend')

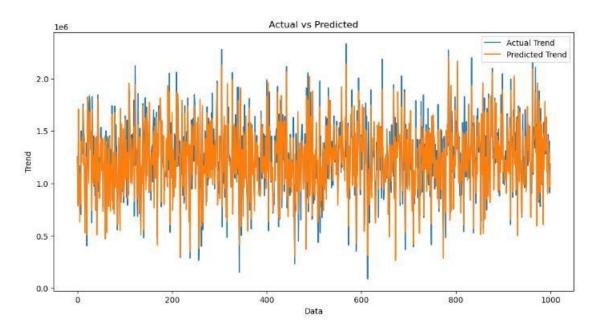

plt.plot(np.arange(len(Y_test)), Prediction5, label='Predicted Trend') plt.xlabel('Data')

plt.ylabel('Trend') plt.legend()

plt.title('Actual vs Predicted')

OUTPUT:
```

Text(0.5, 1.0, 'Actual vs Predicted')

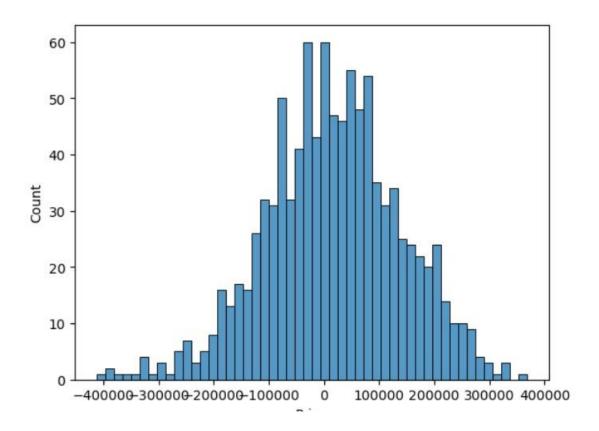

#### INPUT;

```
sns.histplot((Y_test-Prediction4), bins=50)
```

#### OUTPUT:

<Axes: xlabel='Price', ylabel='Count'>

#### CONCLUSION:

This project entitled "House Price Prediction Using XG Boost Regression Model." is useful in buying the houses, by predicting house prices, and thereby to guide their buyers accordingly. The proposed system is also useful to the buyers to predict the cost of house according to the area it is present. XG boosting algorithm has high accuracy value when compared to all other algorithms regarding house price prediction.
